

INDIAN SCHOOL MUSCAT

CLASS XI

INFORMATION TECHNOLOGY(802)

Chapter -1: Computer Organization & OS : User Perspective

Teacher: Saju Jagannath

Some points to keep in mind.....

- Please avoid login from multiple systems.
- Kindly logout at the end of the session.
- Please turn off your mic and webcam
- If you have any doubt, write in the chat box
- If there is any technical problem, hold on – we will be back
- Since it is a lockdown situation you can use rough notebook or notepad or sheets of paper to take down notes. You may take screenshots during the course of delivery of topics.

Inside the computer

Components

Motherboard: This is the main circuit board which holds together various components like CPU, memory, connectors for the hard drive and optical drives, expansion cards to control the video and audio, and connections in the form of various ports (such as USB ports). It provides a connection to every component of the computer. The motherboard houses the main processor or the CPU (Central Processing Unit). CPU executes the user instruction and coordinates amongst all other units of the computer.

There are a variety of processors in the market categorized on the basis of the speed, technology (dual-core, quad-core, octa-core) and their manufacturers (Intel and AMD to name just two). Speed of a processor usually measured in megahertz (MHz) – millions of instructions per second; and gigahertz (GHz) – billions of instructions per second, is indicative of its power.

Power Supply Unit: This component of the computer is the one which converts the alternate current power supply being received by homes or offices to the low voltage direct current required by the machine.

Power Supply Unit

CPU: The motherboard houses the main processor or the CPU (Central Processing Unit). CPU executes the user instruction and coordinates amongst all other units of the computer. Thus, it is primarily responsible for the performance of the machine. There are a variety of processors in the market categorized on the basis of their speed, technology (dual-core, quad-core, octa-core) and their manufacturers (Intel and AMD to name just two).

Speed of a processor usually measured in megahertz(MHz) – millions of instructions per second; and gigahertz (GHz) – billions of instructions per second, is indicative of its power.

Hard disk: It is the secondary storage device for storing the data. The program which is to be executed is first stored in the hard disk from where it is transferred to RAM. On completion of work, the program is again saved on the hard disk.

HARD DISK (HDD)

Two sided view of a sealed hard disk unit

It is usually characterized by the performance and its capacity. Memory capacity is specified in terms of bytes. These days the capacity of a hard disk is expressed in terms of Gigabytes, Terabytes.

Everything in computer is stored in terms of Bits (Binary Digits) i.e 0's and 1's

1 nibble = 4 bits

1 byte = 8 bits

1024 bytes = 1 Kilobyte (KB)

1024 KB = 1 Megabyte (MB)

1024 MB = 1 Gigabyte (GB)

1024 GB = 1 Terabyte (TB)

1024 TB = 1 Petabyte (PB)

1024 PB = 1 Exa Byte (EB)

1024 EB = 1 Zetta Byte (ZB)

COMPACT DISK DRIVE(CD/DVD DRIVE)

Random Access Memory (RAM): This memory storage plays an important role in the functioning of a computer system. Every time you start up the computer, the *operating system* (the system software that manages the device's interaction with the peripherals and the internal resources) is loaded in the RAM.

The program that needs to be executed at any point of time also needs to be brought in the RAM. These days the PCs have around 8-32 GB RAM. More the RAM, more will be the space for the programs leading to faster execution. Of course, everything in computers is subject to some limits.

Operating system

A computer needs to communicate with both the hardware and software; to do this; it utilizes the services of an *Operating system*. Examples of some popular operating system are Windows, Linux, Unix, MS-DOS, SOLARIS, MAC OS. The operating system acts as an interface between the users of the system and hardware of the system.

Operating system continued.....

It also acts like a government which lays down policies for efficient utilization of the resources and provides for effective co-ordination amongst the various components of a computer. Every computer system whether it is an independent system like a desktop or a cell phone must have an operating system for performing the core functionalities like accepting input from various input devices, directing the output to the display, managing the files and directories, communicating with hardware, and installing/ uninstalling of peripheral devices.

Operating system an interface

Functions of an Operating system

The prime functions of an operating system can be broadly categorized as:

- Providing for communication between User and computer
- Resource management
- Process management
- File management
- Memory management

Various tasks of operating system

Communication Manager: Manages the communication needs of the system, be it communicating with the peripheral devices or the internet, are addressed by the operating system. Each of the peripheral devices like printer, mouse have unique characteristics and the computer needs to know these unique properties, to interact with them. For this, the operating system uses special programs called *drivers* which enable recognition of these devices and their properties.

Resource Management: The working of a computer system is predominantly dependent on how its resources are being managed. The resources that we talk of here; are the memory of the computer, the CPU time, files, secondary storage, input/output devices etc. The operating system handles the allocation of all such resources, the priority in which these are allotted to the various processes to get an optimum performance from the system.

Process Management: A process is a program currently executing in the memory or waiting for the CPU. In a computer there are multiple processes in the system. The OS manages, controls, schedules all the processes being executed in the computer. It decides which process gets the processor and for how long.

Memory Management: For a process to be executed, it has to be loaded in the working memory that is the RAM (Random Access Memory). The memory management component of an operating system allocates memory to the processes in a dynamic manner that is allocated on demand and released when not needed.

File Management: Operating system takes care of all the files and folders (directories) maintained on the computer disk. The basic tasks that a user needs to perform on files are creation, renaming, deletion, copying or moving of a file or folder. All the files stored in a computer system can be located through the file system. Two main types of file system are File Allocation table (FAT) or New Technology File system (NTFS).

Types of Operating System

Operating systems can be classified in different ways; depending on various parameters.

Single-tasking and Multi-tasking

Single tasking such operating systems allow execution of only a single program at any given instant. Eg: OS used in mobile phones(Android OS)

Mutli-tasking As the name suggests, can execute more than one programs simultaneously. The processor time, in this case, is divided amongst various processes.

Eg: Windows, Linux

Operating System continued...

Single user and Multi-user

Single-user operating systems allow only one user to use the system. The desktop systems can be classified as typical single user systems.

Eg: Windows, Mac OS X

Multi-user operating systems allow many users to access the system by maintaining an account of all the registered users. Eg: Linux, Unix

Operating System continued...

Real-time Operating System

Operating systems which ensure that the response time is fixed are categorized as real-time operating systems. They are intended for applications where data needs to be processed quickly, without any significant delays. For example, an anti-aircraft missile system must fire as soon as it receives signal from the enemy aircraft, before it leaves the bomb and flies away.

Usage: Traffic Lights control, Heart rate monitoring, Aircraft control, Controlling robots. Eg: IBM's [OS/390](#)

Operating System continued...

Batch Processing Systems

In a batch processing systems, similar jobs are clubbed together and submitted as a block to the processor for execution. User intervention is minimal in such systems. The jobs are picked up one by one and executed.

Usage: Electricity, Gas and telephone bills calculated on a monthly basis. Eg: IBSYS for IBM's 709x

Any Questions?
