## CLASS 12 <br> CHAPTER 4

## CHEMICAL KINETICS

## Chemical Kinetics

The branch of chemistry, which deals with the study of reaction rates and their mechanisms, called chemical kinetics.

Thermodynamics tells only about the feasibility of a reaction whereas chemical kinetics tells about the rate of a reaction.

Kinetic studies not only help us to determine the speed or rate of a chemical reaction but also describe the conditions by which the reaction rates can be altered.
The factors such as concentration, temperature, pressure and catalyst affect the rate of a reaction.

## Rate of a Chemical Reaction

The speed of a reaction or the rate of a reaction can be defined as the change in concentration of a reactant or product in unit time. It can be expressed in terms of:
(i) the rate of decrease in concentration of any one of the reactants, or (ii) the rate of increase in concentration of any one of the products.

The rate of the reaction $=$ Change in concentration of $R$ or $P$
Time taken

## Average rate \& Instantaneous rate

$\square$ Average rate of reaction is the rate measured for larger change in concentration (or) the rate measured for longer time intervals.

$$
\text { Average rate of reaction }=\frac{-\Delta[\mathrm{R}]}{\Delta t}=\frac{\Delta[\mathrm{P}]}{\Delta t}
$$

$\square$ The rate of reaction at a particular instant of time is called as the instantaneous rate,

$$
\text { Instantaneous rate of reaction }=\frac{-d[\mathrm{R}]}{d t}=\frac{d[\mathrm{P}]}{d t}
$$

Dlt is obtained when we consider the average rate at the smallest time interval say dt ( i.e. when $\Delta t$ approaches zero).

## Average rate \& Instantaneous rate

## The Rate Expression of a Chemical Reaction

Consider a general reaction,

$$
R \rightarrow P
$$

One mole of the reactant $R$ produces one mole of the product $P$. If $[R] 1$ and $[P]_{1}$ are the concentrations of reactant and product respectively at time $t_{1}$ and $[R]_{2}$ and $[P]_{2}$ are their concentrations at time $t_{2}$ then,
$\boldsymbol{\Delta t}=\boldsymbol{t}_{2}-\boldsymbol{t}_{1} \quad \boldsymbol{\Delta}[\mathrm{R}]=[\mathrm{R}]_{2}-[\mathrm{R}]_{1} \quad \& \quad \Delta[\mathrm{P}]=[\mathrm{P}]_{2}-[\mathrm{P}]_{1}$
The average rate of the reaction $=\frac{-\Delta[\mathrm{R}]}{\Delta t}=\frac{\Delta[\mathrm{P}]}{\Delta t}$
The instantaneous rate of the reaction $=\frac{-\mathrm{d}[\mathrm{R}]}{\mathrm{dt}}=\frac{\mathrm{d}[\mathrm{P}]}{\mathrm{dt}}$

- Rate of disappearance of Reactant = Rate of reaction
$=$ Decrease in concentration of $R=-\underline{\Delta}[R]$
Time taken $\Delta t$

## Rate of appearance of Product $=$ Rate of reaction

$=$ Increase in concentration of $\mathrm{P}=\Delta[\mathrm{P}]$
Time taken $\Delta t$

Since, $\Delta[R]$ is a negative quantity (as concentration of reactants is decreasing), it is multiplied with $\mathbf{- 1}$ to make the rate of the reaction a positive quantity.

- Consider the reaction

$$
\mathrm{N}_{2}+3 \mathrm{H}_{2} \rightarrow 2 \mathrm{NH}_{3}
$$

Rate of reaction $=-\frac{\Delta\left[N_{2}\right]}{\Delta t}=-\frac{\Delta\left[H_{2}\right]}{3 \times \Delta t}=\frac{\Delta\left[N_{3}\right]}{2 \times \Delta t}$

Rate of disappearance of $\mathbf{N}_{\mathbf{2}}=$ Rate of reaction
Rate of disappearance of $\mathrm{H}_{2}=3 \times$ Rate of reaction
Rate of appearance of $\mathrm{NH}_{3}=2 \times$ Rate of reaction
Q. Write the average and instantaneous rate expressions for the reaction

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5} \rightarrow 4 \mathrm{NO}_{2}+\mathrm{O}_{2}
$$

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5} \rightarrow 4 \mathrm{NO}_{2}+\mathrm{O}_{2}
$$

Average rate of reaction $=\frac{-\Delta\left[\mathrm{N}_{2} \underline{O}_{5}\right]}{2 \times \frac{\Delta}{\Delta t}}=\frac{-\Delta\left[\mathrm{NO}_{2}\right]}{4 \times \Delta t}=\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta \mathrm{t}}$

Average rate of reaction $=-\frac{d\left[N_{2} \underline{O}_{5}\right]}{2 x d t}=-\frac{d\left[\mathrm{NO}_{2}\right]}{4 \times d t}=\frac{d\left[\mathrm{O}_{2}\right]}{d t}$

## Units of rate of reaction:-

If concentration is in $\mathrm{mol} \mathrm{L}^{-1}$ and time is in seconds then the unit of rate is $\mathrm{mol} \mathrm{L}^{-1} \mathrm{~s}^{-1}$.
$\square$ In gaseous reactions, when the concentration of gases is expressed in terms of their partial pressures (atm), then the unit of the rate is atm $\mathbf{s}^{-1}$.
Q. The decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}$ in $\mathrm{CCl}_{4}$ at 318 K has been studied by monitoring the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ in the solution. Initially the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}$ is $2.33 \mathrm{~mol} \mathrm{~L}^{-1}$ and after 184 minutes, it is reduced to $2.08 \mathrm{~mol} \mathrm{~L}^{-1}$. The reaction takes place according to the equation

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5} \rightarrow 4 \mathrm{NO}_{2}+\mathrm{O}_{2}
$$

Calculate,
(i) The average rate of this reaction.
(ii) The rate of disappearance of $\mathrm{N}_{2} \mathrm{O}_{5}$
(iii) The rate of production of $\mathrm{NO}_{2}$ and
(iv) The rate of production of $\mathrm{O}_{2}$
(v) The average rate in terms of hours and seconds.

Answer
(i) The average rate of the reaction $=6.79 \times 10^{-4} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{~min}^{-1}$
(ii) The rate of disappearance of $\mathrm{N}_{2} \mathrm{O}_{5}==1.35 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{~min}^{-1}$
(iii) The rate of production of $\mathrm{NO}_{2}$ and $=2.71 \times 10^{-3} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{~min}^{-1}$
(iv) The rate of production of $\mathrm{O}_{2}=6.79 \times 10^{-4} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{~min}^{-1}$
(v) The average rate in terms of hours and seconds

$$
\begin{aligned}
& =4.074 \times 10^{-2} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{hr}^{-1} \\
& =1.13 \times 10^{-5} \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{sec}^{-1}
\end{aligned}
$$

Q. Consider the formation of ammonia

$$
\mathrm{N}_{2}+3 \mathrm{H}_{2} \rightarrow 2 \mathrm{NH}_{3}
$$

The pressure of hydrogen of this reaction was found to decrease from 20 atm to 8 atm in 100 seconds.

## Calculate

(i) The average rate of this reaction.
(ii) The rate of disappearance of $\mathrm{N}_{2}$
(iii) The rate of disappearance of $\mathrm{H}_{2}$
(iii) The rate of production of $\mathrm{NH}_{3}$ and
(v) The average rate in terms of hours

Answer
(i) The average rate of the reaction $=0.04 \mathrm{~atm} \mathrm{sec}^{-1}$
(ii) The rate of disappearance of $\mathrm{N}_{2}=0.04 \mathrm{~atm} \mathrm{sec}^{-1}$
(iii) The rate of disappearance of $\mathrm{H}_{2}=0.12 \mathrm{~atm} \mathrm{sec}^{-1}$
(iii) The rate of production of $\mathrm{NH}_{3}$ and $=0.08 \mathrm{~atm} \mathrm{sec}^{-1}$
(v) The average rate in terms of hours $=144 \mathrm{~atm} \mathrm{sec}^{-1}$

## Factors affecting the Rate of a Chemical Reaction

1-Nature of reactant
2-Concencentration of Reactants:
Rate of reaction is directly proportional to conc. of reactants
(partial pressure in case of gaseous - phase reactions).
3-Temperature
: Rate of reaction increases with increase in temperature.
4-Presence of Catalyst : A catalyst alters the Rate of a reaction. 5-Surface Area of the Reactants:

Rate of reaction $\propto$ surface area.

Effect of concentration on rate of reaction:
Rate Law (or) Rate expression:
It is a mathematical expression that relates rate of a reaction with rate constant and the concentration of reactants which actually influence the rate.
Consider the reaction $\mathrm{aA}+\mathrm{bB} \rightarrow$ Products
Rate law expression for the reaction is
Rate $\alpha[\mathrm{A}]^{\mathrm{x}}[\mathrm{B}]^{\mathrm{y}}$
Rate $=\mathrm{k}[\mathrm{A}]^{\mathrm{x}}[\mathrm{B}]^{\mathrm{y}}$
where x and y are determined experimentally and cannot be deduced from the balanced chemical equation.
k is rate constant or specific reaction rate.
Rate constant is defined as the rate of reaction when the concentrations of all reactants are unity.

## Rate Constant (k) :

For a general reaction

$$
a A+b B \rightarrow c C+d D
$$

Rate of reaction $=k[A]^{x}[B]^{y}$
Where $k$ is known as rate constant
When $[A]=[B]=1 \mathrm{~mol} / \mathrm{L}$, then

$$
\text { Rate of reaction }=k
$$

thus rate constant of a chemical reaction may be defined as the reaction rate when the concentration of each reactant is unity.
The value of rate constant is definite and constant for a particular reaction at given temperature

## Consider the reaction aA + bB $\rightarrow$ Products

Rate law expression for the reaction is Rate $=k[A]^{x}[B]^{y}$
Differential rate equation for the reaction:
$\frac{-\mathrm{d}[\mathrm{R}]}{\mathrm{axdt}}=\mathrm{k}[A]^{\mathrm{x}}[\mathrm{B}]^{\mathrm{y}}$

## Order of a Reaction

The sum of powers of the concentration of the reactants in the rate law expression is called the order of that chemical reaction.

For a general reaction

$$
a A+b B \rightarrow c C+d D
$$

Rate law is

$$
\text { Rate }=k[A]^{x}[B]^{y}
$$

Here,

$$
x=\text { order of reaction w.r.t. A }
$$

$y=$ order of reaction w.r.t. B
Overall order of reaction $=x+y$
$>$ Order of a reaction can be $0,1,2,3$ and even a fraction.
> Depending upon order of reaction, reactions are termed as zero, first or second order reactions.
> A zero order reaction means that the rate of reaction is independent of the concentration of reactants.
$>$ Order of reaction cannot be predicted by merely from the stoichiometry of balanced chemical equation. Order cannot be predicted theoretically but must be determined experimentally.

Order of reaction and Unit of rate constant:
(i) For zero order reaction rate $=k[A]^{0}$

$$
\mathrm{k}=\text { rate }=\mathrm{mol} \mathrm{~L}^{-1} \mathrm{sec}^{-1}
$$

(Unit of rate constant and rate of reaction are same for zero order reaction)
(ii) For first order reaction $\quad$ rate $=k[A]^{1}$

$$
\mathrm{k}=\frac{\text { rate }}{[\mathrm{A}]}=\frac{\mathrm{mol} \mathrm{~L}^{-1} \mathrm{sec}^{-1}}{\mathrm{~mol} \mathrm{~L}^{-1}}=\sec ^{-1}
$$

Unit of rate constant for first order reaction is
$\sec ^{-1}$ (or) $\mathrm{min}^{-1}$ (or) hour ${ }^{-1}$ (or) $\mathrm{yr}^{-1}$
(iii) For second order reaction

$$
\begin{aligned}
& \text { rate }=\mathrm{k}[\mathrm{~A}]^{2} \\
& \mathrm{k}=\frac{\text { rate }}{[\mathrm{A}]^{2}}=\frac{\mathrm{mol} \mathrm{~L}}{}{ }^{-1} \mathrm{sec}^{-1} \\
& \left(\mathrm{~mol} \mathrm{~L}^{-1}\right)^{2}
\end{aligned}=\mathrm{L} \mathrm{~mol}^{-1} \mathrm{sec}^{-1} .
$$

For $\mathrm{n}^{\text {th }}$ order reaction k has the unit $\left(m o l L^{-1}\right)^{1-\mathrm{n}} \sec ^{-1}$ (or) $\mathrm{M}^{1-\mathrm{n}} \sec ^{-1}$
Q. From the rate expression for the following reaction, determine the order of the reaction and the unit of the rate constants.

$$
3 \mathrm{NO}(\mathrm{~g}) \rightarrow \mathrm{N}_{2} \mathrm{O}(\mathrm{~g})
$$

$$
\text { Rate }=k[\mathrm{NO}]^{2}
$$

Q. Consider a reaction:

$$
2 \mathrm{~A}+\mathrm{B} \rightarrow \mathrm{C}+\mathrm{D}
$$

The reaction is third order in A and second order in B.
(i) Write the rate law expression.
(ii) Also write the differential rate equation
(iii) How is the rate affected on increasing the concentration of A two times?
(iv) How is the rate affected on increasing the concentration of B three times?
(v) How is the rate affected when the concentrations of both A and B are doubled?

## Answer

(i) Rate $=\mathrm{k}[\mathrm{A}]^{3}[\mathrm{~B}]^{2}$
(ii) $-\underline{\mathrm{d}[\mathrm{A}]}=\mathrm{k}[\mathrm{A}]^{3}[\mathrm{~B}]^{2}$

2 xdt
(iii) 8 times
(iv) 9 times
(v) 32 times
Q. The rate of a reaction increases 16 times when the concentration of reactant doubles. Calculate the order of the reaction.
Q. The following results have been obtained during the kinetic studies of the reaction:
$2 \mathrm{~A}+\mathrm{B} \rightarrow \mathrm{C}+\mathrm{D}$

| Experiment | $[A] / \mathrm{mol} \mathrm{L}^{-1}$ | $[B] / \mathrm{mol} \mathrm{L}^{-1}$ | Initial rate of formation of D <br> $\mathrm{mol} \mathrm{L}^{-1} \mathrm{~min}^{-1}$ |
| :---: | :---: | :---: | :---: | :---: |
| I | 0.1 | 0.1 | $6.0 \times 10^{-3}$ |
| II | 0.3 | 0.2 | $7.2 \times 10^{-2}$ |
| III | 0.3 | 0.4 | $2.88 \times 10^{-1}$ |
| IV | 0.4 | 0.1 | $2.40 \times 10^{-2}$ |

Determine the rate law and the rate constant for the reaction.

Rate $=\mathrm{k}[\mathrm{A}]^{x}[\mathrm{~B}]^{y}$

| EXP I | $6 \times 10^{-3}=\mathrm{k}(0.1)^{\mathrm{x}}(0.1)^{\mathrm{y}}$ | ---- Equation 1 |
| :--- | :--- | :--- |
| EXP IV | $2.4 \times 10^{-2}=\mathrm{k}(0.4)^{\mathrm{x}}(0.1)^{\mathrm{y}}$ | ---- Equation 2 |

On dividing $2 / 1$

$$
4=4^{x}
$$

Hence $\mathrm{x}=1$

## Elementary \& complex reactions

Elementary reactions are those which complete in one step while complex reactions are multistep reactions where products are obtained after completion of a sequence of elementary reactions.

## Molecularity of a Reaction

Molecularity of a reaction is simply the number of reacting species (atoms, ions or molecules) involving is an elementary reaction which must collide simultaneously.
Let us consider the following reactions,

| Reaction | Molecularity |
| :--- | :--- | :--- |
| (i) $\mathrm{NH}_{4} \mathrm{NO}_{2} \longrightarrow \mathrm{~N}_{2}+2 \mathrm{H}_{2} \mathrm{O}$ | 1. (Unimolecular) |
| (ii) $2 \mathrm{HI} \longrightarrow \mathrm{H}_{2}+\mathrm{I}_{2}$ 2. (Bimolecular) <br> (iii) $2 \mathrm{NO}+\mathrm{O}_{2} \longrightarrow$  |  |

Since the chances of collision and reaction of more than three molecules at a time are very less, the molecularity greater than three is rare.

For complex reactions, the molecularity is obtained for individual steps, The individual steps are obtained from the mechanism of the reaction

## Rate Law and Mechanism

Consider the decomposition of hydrogen peroxide which is catalysed by iodide ion in an alkaline medium.

$$
2 \mathrm{H}_{2} \mathrm{O}_{2} \frac{\mathrm{I}^{-}}{\text {Alkaline medium }} 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{O}_{2}
$$

The rate equation for this reaction is found to be

$$
\text { Rate }=\frac{-\mathrm{d}\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\mathrm{d} t}=k\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]\left[\mathrm{I}^{-}\right]
$$

(1) $\mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{I}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{IO}^{-}$
(2) $\mathrm{H}_{2} \mathrm{O}_{2}+\mathrm{IO}^{-} \rightarrow \mathrm{H}_{2} \mathrm{O}+\mathrm{I}^{-}+\mathrm{O}_{2}$

For complex reaction, order is given by the slowest step and generally, molecularity of the slowest step is same as the order of the overall reaction
$2 \mathrm{NO}+\mathrm{O}_{2} \rightarrow 2 \mathrm{NO}_{2}$. The rate law for this reaction is
rate $=\mathrm{K}[\mathrm{NO}]_{2}\left[\mathrm{O}_{2}\right]$
propose a mechanism for the above reaction

| Order | Molecularity |
| :--- | :--- |
| 1.It is the sum of the powers to <br> which the conc: terms are raised <br> in the rate law expression. | 1.It is the no: of reacting species <br> involved in simultaneous collision <br> during a reaction. |
| 2. It is determined <br> experimentally <br> 3. Order can be zero | 2. It is a theoretical concept |
| 4. It is determined from the slow |  |
| step in a complex reaction. | 4. It can be determined for all |
| step. |  |
| 5. It explains the mechanism of |  |
| the reaction. | 5.It does not explain the <br> mechanism of the reaction. |

## Integrated Rate Equations

a) Zero order reaction

Zero order reaction means that the rate of the reaction is proportional to zero power of the concentration of reactants. Consider the reaction,

$$
\mathbf{R} \rightarrow \mathbf{P}
$$

Rate $=-\frac{\mathrm{d}[\mathrm{R}]}{\mathrm{dt}}=k[\mathrm{R}]^{0}$
As any quantity raised to power zero is unity

$$
\begin{aligned}
& \text { Rate }=-\frac{\mathrm{d}[\mathrm{R}]}{\mathrm{d} t}=k \times 1 \\
& \mathrm{~d}[\mathrm{R}]=-k \mathrm{~d} t
\end{aligned}
$$

Integrating both sides between proper limits

$$
\int_{R_{0}}^{R} d[R]=-k \int_{0}^{t} d t
$$

$$
[R]-\left[R_{0}\right]=-k t
$$

Or

$$
\left[R_{0}\right]-[R]=k t
$$

Or

$$
k=\frac{[R o]-[R]}{t}
$$

## First Order Reactions

First order reaction means that the rate of the reaction is proportional to first power of the concentration of reactants. Consider the reaction,

$$
\mathbf{R} \rightarrow \mathbf{P}
$$

$$
\text { Rate }=-\frac{\mathrm{d}[\mathrm{R}]}{\mathrm{d} t}=k[\mathrm{R}]
$$

Integrating both sides between proper limits

$$
\text { or } \frac{\mathrm{d}[\mathrm{R}]}{[\mathrm{R}]}=-k \mathrm{~d} t
$$

$$
\begin{aligned}
& \int_{R_{0}}^{R} \frac{d[R]}{R}=-k \int_{0}^{t} d t \\
& \ln [R]-\ln \left[R_{0}\right]=-k t
\end{aligned}
$$

Or

$$
\ln \left[R_{0}\right]-\ln [R]=k t
$$

Or

Or

$$
\begin{aligned}
k t & =\ln \frac{[\mathrm{Ro}]}{[\mathrm{R}]} \\
k & =\frac{1}{\mathrm{t}} \ln \frac{[\mathrm{Ro}]}{[\mathrm{R}]}
\end{aligned}
$$

$$
k=\frac{2.303}{t} \log _{10} \frac{[\mathrm{Ro}]}{[\mathrm{R}]}
$$

$$
\mathbf{k}=\frac{2.303}{\mathrm{t}} \log _{10} \frac{[\mathrm{Ro}]}{[\mathrm{R}]}
$$

$$
\log \frac{[\mathrm{R}]_{0}}{[\mathrm{R}]}=\frac{k t}{2.303}
$$

## Integrated rate expressions in terms of partial pressures (First order gas phase reactions)

consider a typical first order gas phase reaction
$\mathrm{A}(\mathrm{g}) \rightarrow \mathrm{B}(\mathrm{g})+\mathrm{C}(\mathrm{g})$
Let $p_{1}$ be the initial pressure of A and $p_{\mathrm{t}}$ the total pressure at time ' $t$ '.
Integrated rate equation for such a reaction can be derived as:

Total pressure $p_{\mathrm{t}}=p_{\mathrm{A}}+p_{\mathrm{B}}+p_{\mathrm{C}}$
If $x$ atm be the decrease in pressure of $A$ at time $t$ and one mole each of $B$ and $C$ is being formed, the increase in pressure of $B$ and $C$ will also be $x$ atm each

|  | $\mathrm{A}(\mathrm{g})$ | $\rightarrow$ | $\mathrm{B}(\mathrm{g})$ | + |
| :--- | :---: | :--- | :--- | :--- |
| At $t=0$ | $p_{1} \mathrm{~atm}$ |  | 0 atm |  |
| At time $t$ | $\left(p_{1}-\mathrm{x}\right) \mathrm{atm}$ |  | xatm |  |

where, $p_{\mathrm{i}}$ is the initial pressure at time $t=0$.
$p_{\mathrm{t}}=\left(p_{\mathrm{i}}-\mathrm{x}\right)+\mathrm{x}+\mathrm{x}=p_{\mathrm{i}}+\mathrm{x}$
$\mathrm{x}=\left(p_{\mathrm{t}}-p_{\mathrm{i}}\right)$
where, Partial pressure A at time $\mathrm{t}, \mathrm{p}_{\mathrm{A}}=p_{\mathrm{i}}-\mathrm{x}=p_{\mathrm{i}}-\left(p_{\mathrm{t}}-p_{\mathrm{i}}\right)$
$=2 p_{\mathrm{i}}-p_{\mathrm{t}}$

$$
\begin{aligned}
k & =\left(\frac{2.303}{t}\right)\left(\log \frac{p_{\mathrm{i}}}{p_{\mathrm{A}}}\right) \\
& =\frac{2.303}{t} \log \frac{p_{1}}{\left(2 p_{1}-p_{\mathrm{t}}\right)}
\end{aligned}
$$

The half-life of a reaction is the time in which the concentration of a reactant is reduced to one half of its initial concentration. It is represented as $t_{1 / 2}$

## $t_{1 / 2}$ for a Zero Order Reactions

For a zero order reaction, rate constant is given by equation $j c=\frac{[R]_{0}-[R]}{t}$

$$
\text { At } t=t_{1 / 2}, \quad[R]=\frac{1}{2}[R]_{0}
$$

The rate constant at $t_{1 / 2}$ becomes

$$
\begin{aligned}
& k c=\frac{[\mathrm{R}]_{0}-1 / 2[\mathrm{R}]_{0}}{t_{1 / 2}} \\
& t_{1 / 2}=\frac{[\mathrm{R}]_{0}}{2 \pi c}
\end{aligned}
$$

## Half-Life of a Reaction

## $t_{1 / 2}$ for a First Order Reactions

For the first order reaction,

$$
\begin{aligned}
& \text { Ic }=\frac{2.303}{t} \log \frac{[R]_{0}}{[R]} \\
& \text { at } t_{1,2} \quad[\mathrm{R}]=\frac{[R]_{0}}{2}
\end{aligned}
$$

So, the above equation beconnes

$$
\pi c=\frac{2.303}{t_{1} / 2} \log \frac{[R]_{0}}{[R] / 2}
$$

$$
\text { oi } \quad t_{1,2}=\frac{2.303}{f c} \log 2
$$

$$
t_{1,2}=\frac{2.303}{1 c} \times 0.301
$$

$$
t_{1,2}=\frac{0.693}{1 c}
$$

## Pseudo - first order reaction

Reactions which are not truly of the first order but under certain conditions reactions become that of first order are called pseudo unimolecular reaction.
For example: Hydrolysis of ester in presence of acid

$$
\mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}+\mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{CH}_{3} \mathrm{COOH}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}
$$

From this reaction, the rate expression should be

$$
\text { r = k [ester] [ } \left.\mathrm{H}_{2} \mathrm{O}\right]
$$

Since, hydrolysis takes place in the excess of $\mathrm{H}_{2} \mathrm{O}$ and concentration change of $\mathrm{H}_{2} \mathrm{O}$ is negligible practically.
therefore, $r=k^{\prime}$ [ester]
Where $\quad k^{\prime}=k\left[\mathrm{H}_{2} \mathrm{O}\right]$.

Q 1:The decomposition of $\mathrm{NH}_{3}$ on platinum surface $2 \mathrm{NH}_{3} \rightarrow \mathrm{~N}_{2}+3 \mathrm{H}_{2}$ is a zero order reaction with $\mathrm{k}=2.5 \times 10^{-4} \mathrm{molL}^{-1} \mathrm{~S}^{-1}$. What are the rates of production of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ ?

Q2:A reaction is second order in $A$ and first order in $B$.
(i) Write the differential rate equation.
(ii) How is the rate affected
a) on increasing the concentration of $A$ three times?
b) when the concentration of both $A$ and $B$ are doubled?

Q3:A reaction is of second order with respect to its reactant. How will its reaction rate be affected if the concentration of the reactant is
(i) doubled
(ii) reduced to half ?

Q4:The data given below is for the reaction, $2 \mathrm{~N}_{2} \mathrm{O}_{5}(\mathrm{~g}) \rightarrow 4 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})$ at 298 K

| S. <br> No. | $\left[\mathrm{N}_{2} \mathrm{O}_{5}\right]$ <br> $\left(\mathrm{mol} \mathrm{L}^{-1}\right)$ | Rate of disappearance of <br> $\mathrm{N}_{2} \mathrm{O}_{5}\left(\mathrm{~mol} \mathrm{~L}^{-1} \mathrm{~min}^{-1}\right)$ |
| :---: | :--- | :---: |
| 1. | $1.13 \times 10^{-2}$ | $34 \times 10^{-5}$ |
| 2. | $0.84 \times 10^{-2}$ | $25 \times 10^{-5}$ |
| 3. | $0.62 \times 10^{-2}$ | $18 \times 10^{-5}$ |

Determine for this reaction
(i) order of reaction
(ii) rate constant
(iii) rate law.

Q5: For a first order reaction, show that time required for $99 \%$ completion is twice the time required for the completion of $90 \%$ of reaction.
Q6:In a first order reaction, the concentration of the reactant is reduced from $0.6 \mathrm{~mol} \mathrm{~L}^{-1}$ to $0.2 \mathrm{~mol} \mathrm{~L}^{-1}$ in 5 minutes. Calculate the rate constant of the reaction.

Q7:A first order decomposition reaction takes 40 minutes for $30 \%$ decomposition. Calculate its $t_{1 / 2}$ value.
Q8:The following data were obtained during the first order thermal decomposition of $\mathrm{SO}_{2} \mathrm{Cl}_{2}$ at constant volume: $\mathrm{SO}_{2} \mathrm{Cl}_{2(\mathrm{~g})} \rightarrow \mathrm{SO}_{2(\mathrm{~g})}+\mathrm{Cl}_{2(\mathrm{~g})}$. Calculate the rate constant

| Experiment | Time/s | Total pressure/atm |
| :---: | :---: | :---: |
| 1 | 0 | 0.4 |
| 2 | 100 | 0.7 |

Q9:The half-life for decay of radioactive ${ }_{14} \mathrm{C}$ is 5730 years. An archaeological artifact containing wood has only $80 \%$ of the ${ }_{14} \mathrm{C}$ activity as found in living trees. Calculate the age of the artifact.

Q10:A first order reaction has a rate constant value of $0.00510 \mathrm{~min}^{-1}$. If we begin with 0.10 M concentration of the reactant, how much of the reactant will remain aer 3.0 hours?
